## DNA-BINDING INDOLE DERIVATIVES, THEIR PRODRUGS AND IMMUNOCONJUGATES AS ANTICANCER AGENTS

### BACKGROUND OF THE INVENTION

The present invention relates to novel DNA alkylating agents and the prodrugs of these agents which are useful as antitumor agents and DNA labelling agents.

CC-1065 (Fig. 1) was first isolated from *Streptomyces zelensis* in 1981 by the Upjohn Company (Hanka et al., *J. Antibiot.* (1978) 31:1211; Martin et al., *J. Antibiot.* (1980) 33:902; Martin et al., *J. Antibiot.* (1981) 34:1119) and was found to have potent antitumor and antimicrobial activity both *in vitro* and in experimental animals (Li et al., *Cancer Res.* (1982) 42:999; Martin et al. (1981)). CC-1065 binds to double-stranded B-DNA within the minor groove (Swenson et al., *Cancer Res.* (1982) 42:2821) with the sequence preference of 5'-d(A/GNTTA)-3' and 5'-d(AAAAA)-3' and alkylates the N3 position of the 3'-adenine by its CPI left-hand unit present in the molecule (Hurley et al., *Science* (1984) 226:843). Despite its potent and broad antitumor activity, CC-1065 cannot be used in humans because it causes delayed death in experimental animals.

Many CC-1065 analogs have been synthesized. Some of these synthetic analogs are U-73975 (Fig. 1, adozelesin, Aristoff, *Adv. in Med. Chem.* (1993) 2:67); U-77779 (bizelesin, Aristoff (1993)); U-80244 (Fig. 1, carzelesin, Aristoff, (1993)); KW-2189 (Ogasawara et al., *Jpn. J. Cancer Res.* (1994) 85:418); YW-052, YW-053, (Fig. 1, Wang and Lown, *Book of Abstracts-209th Amer. Chem. Soc. National Meeting* (1995)); CBI-CDPI<sub>1</sub> and CBI-CDPI<sub>2</sub> (Boger and Johnson, *Proc. Natl. Acad. Sci. U.S.A.* (1995) 92:3642). U-73975, U-77779 and U-80244 are in clinical trials in the USA (Aristoff, 1993) and KW 2189 is in clinical trials in Japan (Niitani et al., *Proceeding. Amer. Asso. Cancer Res.* (1995) 243). The monoclonal antibody conjugate, DC1 (Fig. 3, Chari, R. V. J., et al., *Cancer Res.*, (1995) 55:4079) has recently been reported.

Another class of related compounds includes netropsin (Julia, M., et al., *Acad. Sci.* (1963) 257:1115) and distamycin (Arcamone, F. M., et al., *Gazz. Chim. Ital.* (1967) 97:1097). Their structures are shown in Fig. 2. Both compounds are positively charged. These compounds are not used as antitumor agents because of their low therapeutic efficacy. A synthetic analog of this class of compound, FCE 24517 (Fig. 2, Arcamone, F. M., et al., *J. Med. Chem.* (1989) 32:774), was reported. FCE 24517 is a conjugate of benzoic acid nitrogen mustard and oligopyrrole, and is currently undergoing clinical trials.

A limitation of currently used antitumor drugs is the lack of selectivity to cancerous cells over normal tissue. It would be desirable to provide high potency compounds which were selective for cancerous cells over normal tissue. It would also be useful to provide labelling agents which selectively label DNA. This invention fulfills these and related needs.

## DESCRIPTION OF THE PREFERRED EMBODIMENT

The following definitions are set forth to illustrate and define the meaning and scope of the various terms used to describe the invention herein.

The term "hydrocarbyl" shall refer to an organic radical comprised of carbon chains to which hydrogen and other elements are attached. The term includes alkyl, alkenyl, alkynyl and aryl groups, groups which have a mixture of saturated and unsaturated bonds, carbocyclic rings and includes combinations of such groups. It may refer to straight chain, branched-chain, cyclic structures or combinations thereof.

The term "alkyl" refers to a branched or straight chain acyclic, monovalent saturated hydrocarbon radical of one to twenty carbon atoms.

The term "lower-alkyl" refers to an alkyl radical of one to six carbon atoms. This term is further exemplified by such radicals as methyl, ethyl, n-propyl, isopropyl, isobutyl, sec-butyl, n-butyl and tert-butyl, n-hexyl and 3-methylpentyl.

The term "alkenyl" refers to an unsaturated hydrocarbon radical which contains at least one carbon-carbon double bond and includes straight chain, branched chain and cyclic radicals.

The term "alkynyl" refers to an unsaturated hydrocarbon radical which contains at least one carbon-carbon triple bond and includes straight chain, branched chain and cyclic radicals.

The term "lower" referred to herein in connection with organic radicals or compounds respectively defines such with up to and including six, preferably up to and including four carbon atoms. Such groups may be straight chain or branched.

The term "aryl" refers to an aromatic carbocyclic radical having a single ring (e.g., phenyl) or multiple condensed rings (e.g., naphthyl).

The term "heterocyclic aromatic" refers to an aromatic mono- or poly-cyclic radical having at least one heteroatom within a ring, e.g., nitrogen, oxygen or sulfur.

For example, typical heteroaryl groups with one or more nitrogen atoms are tetrazoyl, pyrrolyl, pyridyl (e.g., 4-pyridyl, 3-pyridyl, 2-pyridyl), pyridazinyl, indolyl, quinolyl (e.g., 2-quinolyl, 3-quinolyl etc.), imidazolyl, isoquinolyl, pyrazolyl, pyrazinyl, pyrimidinyl, pyridonyl or pyridazinonyl; typical oxygen heteroaryl radicals with an oxygen atom are 2-furyl, 3-furyl or benzofuranyl; typical sulfur heteroaryl radicals are thienyl, and benzothienyl; typical mixed heteroatom heteroaryl radicals are furazanyl, oxazolyl, isoxazolyl, thiazolyl, and phenothiazinyl. Further the term also includes instances where a heteroatom within the ring has been oxidized, such as, for example, to form an N-oxide or sulfone.

The term "ureido" refers to the group  $\text{-NH-C(O)-NH}_2$ .

The term "linker" refers to any chemically and biologically compatible covalent grouping of atoms which can serve to link the compounds of this invention to antibodies or enzyme substrates. Generally, preferred linking groups have from 0-20 carbons, preferably 0-8 carbons, more preferably 0-3 carbons and/or 0-10 heteroatoms (NH, O, S, P etc.) and may be branched or straight chain or contain rings. The linkage can be designed to be hydrophobic or hydrophilic. The linking group can contain single and/or double bonds and saturated or aromatic rings. The linking group may contain groupings such as amide, ester, phosphate, ether, sulfide, disulfide, amine and the like.

The representation " $\omega$ -substituent alkyl" means that the substituent is on the distal (i.e., terminal) carbon of the alkyl chain.

The present invention includes synthesis, biological evaluation and therapeutic use of novel DNA alkylating agents and their prodrugs. The free drugs, which do not need enzyme activation, have potent antitumor activities *in vitro* against U937 leukemia cells and B16 melanoma cells (Tables 1-2).

They are also effective against tumor cells in mice with life-span increase of up to 91%. These compounds shows no sign of delayed death that has limited the clinic use of the natural product CC-1065. Other CC-1065 analogs, U-73975, U-77779, U-80244 and KW 2189, which do not cause delayed death are currently under clinical trials.

One advantage of some of these new compounds is that the hydroxy or amino group on the side chain enhances water solubility. This is an important feature because poor water solubility often causes difficulties in formulation, administration of antitumor agents, and sometimes side effects.

Another advantage of these compounds is that an amide bond at the end of the heterocycle side chain or a double bond connecting the DNA alkylating moiety and the heterocycle side chain increases DNA-binding abilities of these molecules which then increase their antitumor activity. The improved water solubility and increased DNA-binding ability enhances the antitumor activity of these compounds.

Unlike CC-1065, these new compounds are composed of different heterocycles. CC-1065 binds to AT-rich sequences of the DNA. While these new compounds will bind to AT-rich sequences of DNA, they will also bind to other sequences of DNA such as CG or mixed AT and CG sequences of DNA. Thus, the compounds are able to bind to and label DNA.

5 This invention provides monoclonal antibody conjugates and enzyme substrate conjugates of novel highly potent compounds. These conjugates are used to inhibit and prevent tumor growth using monoclonal antibody-directed enzyme prodrug therapy (ADEPT, Bagshawe, *Br. J. Cancer* 1989, 60:272) or antibody-directed catalysis (ADC, Jungheim and Shepherd, 10 *Chem. Rev.* 1994, 94:1553). In these approaches, an enzyme is conjugated to a tumor specific antibody. The antibody selectively localizes the enzyme on the tumor cell surface. Subsequent administration of a prodrug which is a substrate of 15 the enzyme results in the enzyme-catalyzed release of the free drug at the tumor site. This strategy addresses the stoichiometry, controlled drug release and poor antibody penetration problems associated with the use of antibody-drug conjugate alone. In addition, because the process of drug 20 release is enzymatic, a large amount of free drug can be generated by a single enzyme.

The drugs used herein are high potency compounds. Thus, small amounts of antibody and drug can be used. Using a low amount of antibody minimizes immunogenic side effects, 25 alleviates formulation problems, increases the likelihood of drug penetration into the desired tissue and reduces overall cost.

Two examples related to this invention are shown in Fig. 4. The first example is an ADEPT approach employing the 30 enzyme  $\beta$ -glucuronidase. A nitrogen mustard glucuronide was activated by  $\beta$ -glucuronidase or  $\beta$ -glucuronidase-antibody conjugate to generate phenol mustard which is more toxic to cells than the parent compound (Wang, S. M., et al., *Cancer Res.*, 1992, 52:4484). The second example uses  $\beta$ -lactamase to 35 cleave the doxorubicin from its  $\beta$ -lactam prodrug (Jungheim, L. N., et al., *Heterocycles*, 1993, 35:339).

The new DNA alkylating agents invented here are among the most potent antitumor agents ever reported. The

prodrugs in this invention are the first example using these highly potent molecules in an ADEPT approach. This kind of prodrug has several advantages. First very little drug is needed. Second, since minimal amounts of monoclonal antibody-enzyme conjugate are needed, problems due to immunogenicity are reduced.

All of the prodrugs contained in this invention are less toxic than their corresponding free drugs. In the presence of related enzymes or monoclonal antibody-enzyme conjugates such as glucuronidase or  $\beta$ -lactamase these prodrugs will be activated to release the free drugs (Figs. 5 and 6).

Using such potent molecules for monoclonal antibody-drug conjugate has advantages over using low potency agents. The tumor specific antibody will carry these molecules specifically to tumor cells, thus enhancing the therapeutic efficacy of these compounds. The monoclonal antibody-drug conjugates are still very toxic to cancer cells. The Mab-YW-242 conjugates were tested *in vitro* against human liver cancer HepG2 cells.  $IC_{50}$  values for cell proliferation were determined by incorporation of  $^3H$ -thymidine. The results are shown in Table 3.

Generally, the enzyme substrate or antibody is attached to a DNA alkylating agent of this invention by means of a bifunctional linker. "Linking group" shall mean the "chemical arm" between the enzyme substrate and the antibody and the DNA alkylating agent. As one skilled in the art will recognize, to accomplish the requisite chemical structure, each of the reactants must contain the necessary reactive groups.

Representative combinations of such groups are amino with carboxyl to form amide linkages, or carboxy with hydroxy to form ester linkages or amino with alkyl halides to form alkylamino linkages, or thiols with thiols to form disulfides,

or thiols with maleimides or alkylhalides to form thioethers. Obviously, hydroxyl, carboxyl, amino and other functionalities, where not present may be introduced by known methods. Likewise, as those skilled in the art will recognize, a wide variety of linking groups may be employed. The structure of the linkage should be a stable covalent linkage formed to attach the drug or drug derivative to the enzyme substrate and the antibody. In some cases the linking group may be designed to be either hydrophilic or hydrophobic in order to enhance the desired binding characteristics of the ligand and the receptor. The covalent linkages should be stable relative to the solution conditions under which the ligand and linking group are subjected. Generally preferred linking groups will be from 1-20 carbons and 0-10 heteroatoms (NH, O, S) and may be branched or straight chain. Without limiting the foregoing, it should be obvious to one skilled in the art that only combinations of atoms which are chemically compatible comprise the linking group. For example, amide, ester, thioether, thioester, keto, hydroxyl, carboxyl, ether groups in combinations with carbon-carbon bonds are acceptable examples of chemically compatible linking groups. Other chemically compatible compounds which may comprise the linking group are set forth in U.S. Patent Nos. 5,470,997 (col. 2 and col. 4-7); 5,470,843 (cols. 11-13); and 5,470,932.

Representative spacers which can be used to attach an enzyme substrate by acylation or alkylation of the terminal oxygen or nitrogen atom include the following:

-CH<sub>2</sub>OH, -CH<sub>2</sub>CH<sub>2</sub>OH, -CH<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>OH, -CH<sub>2</sub>CH(CH<sub>3</sub>)OH, -CH<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>OH, -CH<sub>2</sub>CH(CH<sub>3</sub>)CH<sub>2</sub>OH, -CH<sub>2</sub>CH<sub>2</sub>CH(CH<sub>3</sub>)CH<sub>2</sub>OH, -C<sub>6</sub>H<sub>10</sub>OH, -C<sub>6</sub>H<sub>4</sub>OH and -CH<sub>2</sub>C<sub>6</sub>H<sub>4</sub>OH; and -CH<sub>2</sub>NH<sub>2</sub>, -CH<sub>2</sub>CH<sub>2</sub>NH<sub>2</sub>, -CH<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>NH<sub>2</sub>, -CH<sub>2</sub>CH(CH<sub>3</sub>)NH<sub>2</sub>, -CH<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>NH<sub>2</sub>, -CH<sub>2</sub>CH(CH<sub>3</sub>)CH<sub>2</sub>NH<sub>2</sub>, -CH<sub>2</sub>CH<sub>2</sub>CH(CH<sub>3</sub>)CH<sub>2</sub>NH<sub>2</sub>, -C<sub>6</sub>H<sub>10</sub>NH<sub>2</sub>, -C<sub>6</sub>H<sub>4</sub>NH<sub>2</sub> and -CH<sub>2</sub>C<sub>6</sub>H<sub>4</sub>NH<sub>2</sub>.

In addition to glucuronidase and B-lactamase substrates, other substrates which can be linked to a DNA alkylating agent of this invention and their corresponding enzymes include glutamic acid for carboxypeptidase, phosphate (phosphoric acid) for alkaline phosphatase, α-galactose for α-

galactosidase and nitrobenzyl carboxylate ( $-C(O)OCH_2C_6H_5NO_2$ ) for nitroreductase.

The compounds of the present invention can be used as antitumor agents. The *in vitro* and *in vivo* antitumor activities presented here demonstrate the validity of this statement. They are also of utility in alkylating, labelling, detecting and isolating DNA.

Thus, the novel compounds and conjugates provided by the present invention may be incorporated into aqueous solutions for injection (intravenous, subcutaneous and the like) or intravenous infusion or into ointment preparations for administration via the skin and mucous membranes. The conjugates of this invention are administered at a therapeutically effective dosage, i.e., that amount which, when administered to a mammal in need thereof, is sufficient to effect treatment, as described above (for example, to reduce or otherwise treat the disease, e.g., control or inhibit tumor growth when cancer is being treated). Administration of the active compounds and salts described herein can be via any of the accepted modes of administration for agents that serve similar utilities.

The level of the drug in a formulation can vary within the full range employed by those skilled in the art, e.g., from about 0.01 percent weight (%w) to about 99.99%w of the drug based on the total formulation and about .01%w to 99.99%w excipient. Preferably the drug is present at a level of about 10%w to about 70%w.

Generally, an acceptable daily dose is of about 0.04  $\mu$ g to 50 mg per kilogram body weight of the recipient per day with lower doses in the range of 0.08  $\mu$ g -10  $\mu$ g being preferred. Thus, for administration to a 70 kg person, the dosage range would be about 28  $\mu$ g to 3.5 g per day. Such use and optimization is well within the ambit of those of ordinary skill in the art. (Fleming, et al., J. Nat. Cancer Institute, 1994, 86(5):368).

Administration can be via any accepted systemic or local route, for example, via parenteral, intravenous, nasal, bronchial inhalation (i.e., aerosol formulation), transdermal

or topical routes, in the form of solid, semi-solid or liquid dosage forms, such as for example, tablets, suppositories, pills, capsules, powders, solutions, suspensions, aerosols, emulsions or the like, preferably in unit dosage forms suitable for simple administration of precise dosages. Administration by intravenous or subcutaneous infusion is usually preferred. Most usually, aqueous formulations will be used. The compounds and conjugates are formulated in a non-toxic, inert, pharmaceutically acceptable carrier medium, preferably at a pH of about 3-8, more preferably at a pH of about 6-8. Generally, the aqueous formulation will be compatible with the culture or perfusion medium. The compositions will include a conventional pharmaceutical carrier or excipient and a compound or conjugate of the DNA alkylating agent, and in addition, may include other medicinal agents, pharmaceutical agents, carriers, adjuvants, etc. Carriers can be selected from the various oils, including those of petroleum, animal, vegetable or synthetic origin, for example, peanut oil, soybean oil, mineral oil, sesame oil, and the like. Water, saline, aqueous dextrose or mannitol, and glycols are preferred liquid carriers, particularly for injectable solutions. Suitable pharmaceutical carriers include starch, cellulose, talc, glucose, lactose, sucrose, gelatin, malt, rice, flour, chalk, silica gel, magnesium stearate, sodium stearate, glycerol monostearate, sodium chloride, dried skim milk, glycerol, propylene glycol, water, ethanol, and the like. Other suitable pharmaceutical carriers and their formulations are described in REMINGTON'S PHARMACEUTICAL SCIENCES by E. W. Martin (1985).

If desired, the pharmaceutical composition to be administered may also contain minor amounts of non-toxic auxiliary substances such as wetting or emulsifying agents, pH buffering agents and the like, such as for example, sodium acetate, sorbitan monolaurate, triethanolamine oleate, etc.

The compounds of this invention are generally administered as a pharmaceutical composition which comprises a pharmaceutical excipient in combination with the DNA alkylating agent or conjugate thereof. The level of the

conjugate in a formulation can vary within the full range employed by those skilled in the art, e.g., from about .01 percent weight (%w) to about 99.99%w of the drug based on the total formulation and about .01%w to 99.99%w excipient.

- 5 Preferably, the formulation will be about 3.5 to 60% by weight of the pharmaceutically active compound, with the rest being suitable pharmaceutical excipients.

A "pharmaceutically acceptable salt" may be any salt derived from an inorganic or organic acid or base. Salts may  
10 be derived from acids or bases.

The acid addition salts are derived from inorganic acids, such as hydrochloric acid, hydrobromic acid, sulfuric acid (giving the sulfate and bisulfate salts), nitric acid, phosphoric acid and the like, and organic acids such as acetic  
15 acid, propionic acid, glycolic acid, pyruvic acid, oxalic acid, malic acid, malonic acid, succinic acid, maleic acid, fumaric acid, tartaric acid, citric acid, benzoic acid, cinnamic acid, mandelic acid, methanesulfonic acid, ethanesulfonic acid, salicylic acid, p-toluenesulfonic acid,  
20 and the like.

The base addition salts are derived from inorganic bases such as sodium hydroxide, potassium hydroxide, lithium hydroxide, ammonia, calcium hydroxide, magnesium hydroxide and the like. Cations derived from organic bases include those  
25 formed from primary, secondary and tertiary amines, such as isopropylamine, diethylamine, trimethylamine, triethylamine, pyridine, cyclohexylamine, ethylene diamine, monoethanolamine, diethanolamine, triethanolamine, and the like.

As used herein, the terms "treatment" or "treating" of a condition and/or a disease in a mammal, means:  
30

- (i) preventing the condition or disease, that is, avoiding any clinical symptoms of the disease;  
(ii) inhibiting the condition or disease, that is, arresting the development or progression of clinical symptoms;  
35 and/or  
(iii) relieving the condition or disease, that is, causing the regression of clinical symptoms.

As used herein, the term "therapeutically effective amount" refers to that amount of a compound of the invention which, when administered to a mammal in need thereof, is sufficient to effect treatment (as defined above) as an anticancer agent, an antimicrobial agent or a DNA alkylating agent. The amount that constitutes a "therapeutically effective amount" will vary depending on the compound, the condition or disease and its severity, and the mammal to be treated, its weight, age, etc., but may be determined routinely by one of ordinary skill in the art with regard to contemporary knowledge and to this disclosure.

The following examples are presented to describe the preferred embodiments and utilities of the present invention and are not meant to limit the present invention unless otherwise stated in the claims appended hereto.

The compounds are generally made by linking together  $R_2$  and the heterocyclic aromatic groups  $R_3$  in the desired order using protecting groups as needed and then attaching the  $R_1$  group. In some cases,  $R_4$  can behave as a protecting group. Coupling of the various units in the chain is typically accomplished using routine peptide bond forming reactions, e.g., carbodiimide mediated coupling conditions, known to those of skill in the art. Additional protecting groups other than those used herein can be found in Protective Groups in Organic Synthesis, 2nd ed. (John Wiley and Sons, Inc., New York, NY, 1991). Exemplary synthetic sequences are shown in Figures 7 and 8.

Isolation and purification of the compounds and intermediates described herein can be effected, if desired, by any suitable separation or purification procedure such as, for example, filtration, extraction, crystallization, column chromatography, preparative high pressure liquid chromatography (preparative HPLC), thin-layer chromatography or thick-layer chromatography, or a combination of these procedures, referred to hereinafter as "conventional means". Specific illustrations of suitable separation and isolation procedures can be had by reference to the examples

hereinbelow. However, other equivalent separation or isolation procedures can also be used.

The starting materials and reagents used in preparing the compounds of this invention are either available from commercial suppliers such as Aldrich Chemical Co. or are prepared by methods known to those skilled in the art following procedures set forth in references such as, "Fieser and Fieser's Reagents for Organic Synthesis", Volumes 1-15, John Wiley and Sons, 1991; "Rodd's Chemistry of Carbon Compounds", Volumes 1-5 and Supplementals, Elsevier Science Publishers, 1989; "Organic Reactions", Volumes 1-40, John Wiley and Sons, 1991 and "Comprehensive Heterocyclic Chemistry", Volumes 1-8 by Katritzki and Rees, Pergamon Press, 1984.

##### Cytotoxicity to Cancer Cells

Some of the new compounds were tested for their cytotoxicity against cancer cells. U937 cells were used to determine the  $\text{IC}_{50}$  values. The assay was set up in triplicate in 96 well flat bottom microtiter plates. All cells are seeded at  $5 \times 10^3$  cells/well in RPMI-1640 plus 10% FCS. Drugs were added and the total volume was adjusted to 0.2 mL/well. Total incubation time was 48 h with the addition of  $^3\text{H}$ -thymidine for the last 24 h of incubation. The assay was harvested and counted with the packard Matrix 96 beta counter. The results were expressed as the percent growth inhibition calculated from the percent decrease in cpm of treated cells relative to the untreated controls.

The results are shown in Fig 9.

#### Example 23

##### Synthesis of YW-242-monoclonal Antibody Conjugates

YW-242 exerts its antitumor activity by binding in the minor groove of DNA. Therefore the drug has to be released from the Mab-drug conjugate after entering cells. A disulfide linker meets this requirement, and is used to connect YW-242 and MAb 3A5 (Fig. 11)

a). Thiolation of Mabs. Mab 3A5 was made according to the reported procedure. (Li et al., *Acta Pharmaceutica Sinica* 1993, 28:260). 3-(2-Pyridyldithio)propionic acid N-hydroxysuccinimide ester (SPDP, 0.152 mg) in ethanol (50  $\mu$ L) was added to Mab 3A5 (2 mg) in PBS (2 mL) and the reaction mixture was incubated for 30 min at 37°C. The mixture was cooled to 0°C and then treated with dithiothreitol (0.45 mg in 50  $\mu$ L of PBS) for 15 min at 4°C. The thiolated Mab was separated by gel filtration chromatography (Sephadex-G 25).

b). Thiolation of YW-242. YW-242 (0.5 mg in 83  $\mu$ L of DMF) was added to SPDP (5.3 mg, 1 mol. equivalent to YW-242, in 0.263 mL of ethanol) and the reaction mixture was incubated for 30 min at 37°C. The product was used without further purification.

c). Conjugation of MAb and the drug. Thiolated YW-242 was added to the thiolated Mabs in PBS and the reaction mixture was allowed to react overnight at 4°C. The reaction mixture was then dialyzed in PBS (1000 mL) for 6 h (PBS was changed every 2 h). The amount of drug bound to Mab was analyzed by UV absorbance and the concentration was calculated. The number of drug molecules conjugated per Mab is 2.7.

#### **Example 24** **Cytotoxicity Studies of the YW-242-monoclonal Antibody Conjugates against Liver Cancer HepG2 Cells**

The conjugates were tested *in vitro* against human liver cancer HepG2 cells. IC<sub>50</sub> values for cell proliferation were determined by incorporation of <sup>3</sup>H-thymidine. 4 x 10<sup>4</sup> of trypsinized cells in 0.1 mL of DMEM medium containing 10% of heat-inactivated FCS were added to each well of 96-well

microtiter plates and incubated for 4 h at 37°C to allow attachment of the cells. Drugs in 10  $\mu$ L of PBS were added and incubated for 1 h at 37°C. Medium was removed and the cells were washed with PBS (0.2 mL). Fresh medium (0.1 mL) and  $^3$ H-thymidine (10  $\mu$ L) were added. The cells were incubated overnight at 37°C. The cells were treated with trypsin-EDTA for 15 min at 37°C and then harvested using a micromate 196 harvester. Radioactivity was counted and IC<sub>50</sub> values were determined. The results are shown in Table 3.

The immunoconjugate Mab-YW-242 is 2.5-fold less toxic than the free drug YW-242. This reduced cytotoxicity is expected because the Mab-drug conjugate is usually less toxic than the free drug in this kind of assay. These results indicates that the Mab-drug conjugate binds to the cell and the free drug is released inside cells. The Mab-drug conjugate is more than 10-fold more potent than doxorubicin.
